A. K. TRIPATHI* & S. N. PANDEY**: A note on the taxonomy of *Arthrospira* and its new species *A. intermedia* (Cyanophyceae) from India

In the family Oscillariaceae, there are three genera viz., *Oscillatoria* Vaucher, *Arthrospira* Stizenberger and *Spirulina* Turpin em. Gardner. *Oscillatoria* was considered as an independent genus since long but there was a controversy regarding *Arthrospira* and *Spirulina*. Geitler (1932) recognized the genus *Spirulina* and divided it into two sections viz., Euspirulina and Arthrospira. At present (Desikachary 1959), however, *Arthrospira* and *Spirulina* are treated as independent genera. So far as *Oscillatoria* is concerned there are certain species which also share the character of *Arthrospira*. The present paper deals with the distinction between *Oscillatoria* and *Arthrospira* and an interesting new species of *Arthrospira*. A Camera Lucida diagram and a photograph of the new taxon are given to facilitate easy identification.

**Arthrospira intermedia** Tripathi et Pandey, sp. nov.

Trichotomata 100-150 \( \mu \text{m} \) longa, cyaneo-viridia, ordinatim spiratim circinata, plerumque stricta vel leviter flexa, haud constricta, 3-4 \( \mu \text{m} \) lata; spirae 4.5-6 \( \mu \text{m} \) latae, 32-36 \( \mu \text{m} \) semotae; cellulae parvae, 2-3 \( \mu \text{m} \) longae, sine valuolae gaseosae; septa non granulata; cellulae extremae rotundatae, leviter attenuatae; calyptrae absentes.

Habitatio: Libere natantia piscina Kalyanpurensis tempore menses August et September 1983.

Iconotypus: Figurae 1, A-C & 2.

The new species is similar to *Arthrospira gomontiana* Setchell in respect of the broadness of spirals as well as trichomes but can be easily distinguished in having 1) spirals more distant, 2) cells shorter in length and 3) cross walls not granulated. It resembles *Arthrospira gomontiana* Setchell var. *crassa*

** Botany Department, D. A-V. College, Kanpur-208001, India.
Gupta, in the breadth of trichomes and the length of cells but differs in 1) spirals less broad and 2) spirals more distant. The new taxon comes closer to Arthrospera joshii Vasishta, in the length of cells and cross walls not granulated but differs in 1) spirals less broad, 2) spirals more distant, 3) trichomes less broad and 4) absence of gas-vacuoles. It comes closer to Arthrospera massartii Kuffareth in the following respects: 1) length of cells, 2) cross walls not granulated and 3) absence of gas-vacuoles but differs in possessing 1) narrower trichomes and 2) narrower distance and magnitude of spirals.

The present species is based on the character having narrower dimensions and distance of the spirals as compared to A. massartii Kuffareth, while the distance of spirals is just about twice in comparison to other taxa, A. gomontiana, A. gomontiana var. crassa and A. joshii. Thus, this species is placed in between these two.
groups of *Arthroversa* and named *Arthroversa intermedia*.

**Discussion** During the course of studies of algal flora of certain polluted ponds of Kanpur there was a problem on the name of a taxon, which has been later on identified as *Arthroversa intermedia*, sp. nov. Some members of Oscillatoria such as *O. boryana*, *O. martini* and *O. formosa* f. *loktakensis* show spirally coiled trichomes, a character of *Arthroversa*. Vasishta (1963) compared *O. martini* with *A. massartii* and found that these two resemble each other in having 1) spirally coiled trichomes, 2) similar dimensions of the trichomes, 3) similar length of cells, and 4) absence of gas-vacuoles and septa not granulated but the former differs from the latter in slight attenuation of the trichomes and the presence of calyptra. It has also been mentioned by him (Vasishta 1963) that the trichomes of *A. massartii* seem to be attenuated at the ends as it appears in the figures drawn by Kuffareth (Desikachary 1959) and in *A. massartii* var. *indica* Desikachary the presence of calyptra has been recorded. Desikachary (1959) in his monograph mentioned that in *Arthroversa* calyptra is absent but he created a new variety, as mentioned above (*A. massartii* var. *indica*), having calyptra. Thus these two different types of statement created a problem to separate *Arthroversa* from *Oscillatoria*. After a comparison of *Arthroversa* with *Oscillatoria*, Vasishta (1963) remarked that “There seems to be no justification in separating *Arthroversa* from *Oscillatoria*. The septate, non-sheathed, spirally coiled trichomatous forms of the Oscillatoriaceae can be put under the genus *Oscillatoria* without incurring any phylogenetic or taxonomic aberration.” However, in the same paper, he (Vasishta 1963) created five new species, including *Arthroversa joshii* and *Oscillatoria mehraii*, and treated *Arthroversa* and *Oscillatoria* as separate genus. This contradictory line of thinking in the same paper indicated that his argument for submission of *Arthroversa* with *Oscillatoria* is not complete because he himself (Vasishta 1963) did not follow on his own argument and he left the problem by stating that “... it would be premature to make any concrete taxonomic suggestions in this paper.”

Literature shows that the trichomes of some species of *Oscillatoria* are either bent or curved or spirally coiled only at the apices. This should be used as a character of the genus *Oscillatoria*. Those species of *Oscillatoria* which show spiral-like twisting only at the ends of their trichomes are *O. ornata*, *O. curviceps*, *O. anguina*, *O. proboscidea*, *O. grunowiana*, *O. willei*, *O. trebriformis*,
O. boryana and O. chalybea. The authors consider that Arthrospira is distinct from Oscillatoria in having spiral coiling spreaded throughout the length of trichomes and this feature can be used as a diagnostic criterion. It may be added here that on a similar ground (for practical convenience) Setchell & Gardner (1919) had segregated Arthrospira from Spirulina.

Vasishta (1963) doubted O. deflexa W. et G. S. West as a species of Arthrospira but the description of O. deflexa (Desikachary 1959) shows that “Trichomes single, or arranged in spirally coiled bundles, ....” It does not mean that a single trichome of O. deflexa is spirally coiled but the bundles of the alga is in spiral manner. Geitler’s (1932) drawing do not show spiral trichomes for the alga and thus no question arises about its validity.

Geitler (1932) mentioned as follows about three species of Spirulina (under the section Arthrospira) which appeared at first instance as the members of Oscillatoria. The trichomes of Spirulina curta (Lemmermann) Geitler are half S-shaped. Those of S. breviarticulata (Setch. et Gardner) Geitler are more or less spirally coiled throughout the length but not in a regular manner. The trichomes of S. schroederi Koppe are straight and uncoiled at the apices while in the middle regularly spiral. On the basis of the spiral trichomes, Geitler (1932) placed these species in the genus Spirulina (section Arthrospira).

Certainly, there is a problem about the placement of some species of Oscillatoria viz., O. martini, O. boryana and O. formosa f. loktakensis. The trichomes of these species do not show a regular manner of spirals though they are not straight but distinctly spiral throughout the length of trichomes. The authors feel that this character, i.e. the spiral nature of trichomes, is sufficient to assign these taxa to the genus Arthrospira, however, they appear to occupy an intermediate position between Arthrospira and Oscillatoria. In the same line the authors are of humble opinion that the species of Oscillatoria which show the spiral nature throughout the length should be transferred to the genus Arthrospira.

Arthrospira martini (Frémy) Tripathi et Pandey, comb. nov.

The trichomes of O. martini Frémy are spirally coiled throughout the length. This species should be treated as a separate species from A. massartii because it has calyptrate trichomes.
var. *indica* (Desikachary) Tripathi et Pandey, comb. nov.

*A. massartii* Kuffareth var. *indica* Desikachary is to be transferred to *A. martini* (Frémy) Tripathi et Pandey, because this taxon shows the presence of calyptra, and it comes closer to the species *A. martini* (Frémy) Tripathi et Pandey.

*Arthrospira boryana* (Bory ex Gomont) Tripathi et Pandey, comb. nov.

According to Desikachary (1959), the trichomes are either coiled as screw-like or bent at the apices or somewhat straight. The authors are of opinion that this variable nature stated for this taxon might be caused by the observation of a mixture of different algae. Vasishta (1963) states that “There are instances where the trichomes are spirally coiled in one region and straight or bent in the rest of the portion. I have often observed the hormogones of *Arthrospira* germinating to give rise to straight *Oscillatoria* like trichomes, e.g. in *Arthrospira khanna* Drouet et Strickland, *A. platensis* (Nordst.) Gomont and *A. joshii* Vasishta.”

*Arthrospira loktakensis* (Bruhl et Biswas) Tripathi et Pandey, comb. nov.

The figure drawn by Biswas (in Desikachary 1959) shows that the trichome *O. formosa* f. *loktaensis* is spirally coiled and, therefore, it should be transferred to *Arthrospira* as a separate species, *A. loktaensis*.

The authors thank the Principal, D.A.V. College, Kanpur for necessary research facilities and to Dr. G.L. Tiwari, Botany Department, Allahabad University, Allahabad for fruitful suggestions and also for kindly going through the manuscript. They also thank Dr. N.P. Balakrishnan, Scientist ‘D’, Flora Cell, Botanical Survey of India, Department of Environment, New Delhi for latin transcription.
